The TuneUpInfluence of glycemc treatment on food intake and weight gain in type 2 diabetes. To assess the influence of different glycemc treatments on food intake and weight change during a 26-week period in patients with type 2 diabetes. Weight and food intake (7-day diary) were recorded at week 1, 5, 12, and 26 for nine patients treated with a single oral antidiabetic agent and ten patients treated with oral antidiabetic agents in combination with insulin at the time of study entry. An additional 24 patients with type 2 diabetes, including seven who had never been treated with oral antidiabetic agents, were recruited to study the changes in food intake and weight during a 26-week period. With a single oral agent, food intake increased, as did weight gain, after 12 weeks and remained constant at 26 weeks. In the group treated with an oral agent and insulin, food intake remained constant during the first 12 weeks of the study, but a marked and sustained weight loss was observed between weeks 12 and 26. A sustained weight loss was not observed in the patients who had never been treated with an oral agent. Initial glycemc treatment with single oral agents leads to increased food intake and weight gain. In contrast
